EDUCATION

University of Georgia

Computer Science – Bachelor of Science, Graduated May 2020

Athens, GA

August 2016 – May 2020

Certifications – UGA Certificate of Applied Data Science, Microsoft Azure Data Engineer Associate (DP-200, DP-201)

SKILLS

Programming Languages – Proficient: Java, JavaScript/ES6, TypeScript, Python, HTML/CSS, Functional-Style, Kotlin |

Intermediate: C/C++, C#

Technologies/Environments – UNIX environment, React, Redux, Next.js, REST APIs, Git, Node.js, MongoDB, Express.js, SQL, AWS, .NET, Angular, Azure Cloud, Django, NumPy, Pandas, Scikit-learn, Keras, TensorFlow

ABOUT ME

Summary – I am a passionate and skilled learner, and I have a keen instinct for aesthetic, product design and user experience. I am interested in a career in data science and machine learning or software engineering.

Relevant Coursework – Multivariable Calculus, Discrete Math, Applied Linear Algebra, Data Science I and II, Systems Programming, Artificial Intelligence, Data Structures, Intro to Theory of Computation

EXPERIENCE

Bank of America

New York, NY

Full Stack Software Engineer

April 2025 – Present

- Led the build of a startup-style dashboard team to construct an end-to-end data visualization dashboard product.
- Designed and implemented data pipelines & associated API (written in Node.js) to ingest, validate and shape/transform large complex JSON payment datasets, ensuring correct/efficient delivery into frontend.
- Developed customizable data agnostic React components wrapping D3.js React component library (Recharts) to render interactive payment-flow graphs, showing various clearinghouse acceptances, settlement status and latency.
- Engineered differing client and administrator facing views to meet needs of a wide internal customer base; marketed the platform internally through various channels driving measurable user growth.
- Currently implementing GPT-5 hookup which provides in-app AI-powered data summary and actionable insights based on known payment heuristics.

Home Depot

Contract (Remote)

Full Stack Software Engineer

March 2024 – November 2024

- Implemented React components for the gift cards checkout flow and experience on Home Depot's website.
- Designed and implemented React components for redesigned checkout experience (Nucleus Checkout) resulting in improved customer satisfaction and checkout time.
- Implemented bug fixes for faulty React components (data flow issues typically) and worked on bug fixes for GraphQL backend API.
- Wrote API routes for Node.js based GraphQL backend engine resulting in fluid and speedy data transfer to frontend components.

AT&T

Remote

Senior Specialist - Software Engineer, CSO (Chief Security Office)

December 2021 – January 2024

- Designed and developed features for AT&T internal security application (Milestone 0) written in React on the frontend and Node.js on the backend.
- Implemented customizable frontend React components for developer use across various facets of Milestone 0 enabling swift development of new features.
- Implemented auth and data fetch routes for a backend Node.js API corresponding with a SQL database enabling rapid payload delivery to the frontend.
- Implemented an LLM-based chat feature into Milestone 0 (written in Python) to assist users with cybersecurity questions resulting in positive user feedback and driving user growth to the platform.
- Wrote and deployed Python scripts to track and plot Milestone 0 application site-access metrics resulting in material measurements in user growth.

- Assumed leadership responsibilities such as timely code review and mentorship resulting in user-story velocity improvements.

Fiserv Contract (Remote)
Full-Stack Software Engineer September 2021 – December 2021

- Implemented data hookup (initial request, reshape data to components' needs, hydrate asynchronously) from backend Java API into frontend React components resulting in a fluid data-driven display of banking transactions.
- Implemented and deployed bug fixes for an expansive enterprise level backend Java codebase.
- Worked with colleagues to oversee the initial stages of a full Java backend codebase refactor and rewrite.

myMatrixx (startup) Contract (Remote)
Junior Full-Stack Developer January 2021 – July 2021

- Implemented search functionality for prescription authorizations within the myMatrixx patient portal via React components resulting in measurable boosts in customer satisfaction after shipment.
- Worked on the server-side myMatrixx prescription sorting engine (written in Java) enabling speedy processing of patient requests.
- Parsed through backend Java code to diagnose and fix slow-executing API calls, among other bugs.
- Worked in a fast-paced agile environment to design, develop and demo features for customers.
- Moved at a rapid pace prototyping features with a small coordinated team in a startup environment.

Blizzard Entertainment Irvine, CA (Virtual due to COVID-19)
Software Engineering Intern, Esports Platform June 2020 – August 2020

- Built out frontend data visualizations for Blizzard Game Data API (GDAPI), written in React and TypeScript; facilitated deployment to AWS.
- Used D3.js to construct a user-customizable time-series visualization of errors thrown by GDAPI resulting in reductions in time spent diagnosing GDAPI bugs.
- Built GDAPI endpoint-agnostic React components to fetch API data and render it in succinct visualizations; allows for the creation of metrics dashboards for any GDAPI application endpoint.

PROJECTS

Trade-GPT, Transformer based equities model – Personal Project New York, NY [April 2025 – Present]

- Ingested 15 years of SPY OHLCV candles; adjusted for corporate actions; removed after hours data; stored in Pandas DataFrame.
- Split candles into input and output horizon with stride overlap (e.g. 10 past candles input and next five candles output); engineered features using Python library ta-lib: volatility (EWMA/ATR), trend/momentum (RSI, MACD, stochastics, SMA/EMA crossovers), mean reversion (Bollinger z-scores).
- Transformed/shaped data into token-efficient prompts to be received by LLM; output: max_up or max_down in bps.
- Fine-tuned an LLM (GPT-5) with inputs/outputs – designed to give max_up or max_down within the output horizon; discovered hyperparameters (input horizon length, output horizon length, stride, and timeframe) with loss function; grid search with each finetune with custom hyperparameters outputting loss.
- WIP: training custom transformer on stock data directly with objective being output bps over output horizon.

Quantitative Equities Trading Model – Personal Project Alexandria, VA [September 2023 – December 2024]

- Pulled millions of historical 5-minute candles for the 30 most traded stocks and indices; analyzed 100+ technical indicators, then applied the 10 most significant indicators to stock candles to generate training data.
- Used PyTorch optimized for GPUs (and Google Cloud Tesla T4) to train a deep neural net which outputs expected stock price movement for a given technical environment
- Used sk-learn grid-search to tweak hyper-parameters until a profit was consistently being generated on validation data

PickupU, A Smarter Way to Play University Recreational Sports – Personal Project Athens, GA [September 2018]

- Developed an application which facilitates recreational sports matches between university students at the University of Georgia.
- A backend (written in Node.js) generates events of various times and activity types (such as basketball, soccer, tennis) – then a matching algorithm places students into events based on their skill-level.
- The idea was pitched to the athletic department and gained approval to be used by students – giving us (founders) expanded control at recreational facilities.
